# ABSTRACT **Objective:** To evaluate the impact of the 2011 Great East Japan Earthquake on body mass index of preschool children. Design: Retrospective cohort study and ecological study. Setting: Affected prefectures (Fukushima, Miyagi and Iwate) and unaffected prefectures in northeastern Japan. **Participants:** The study assessed a total of 2033 boys and 1909 girls from 310 nursery schools located in 3 affected prefectures and a total of 1707 boys and 1658 girls from 238 nursery schools located in 3 unaffected prefectures, all aged 3-4 years at the time of the earthquake. Primary and secondary outcome measures: Post-disaster changes in body mass index (BMI) were compared between children living in affected and unaffected prefectures. **Results:** One month after the earthquake, increased BMIs were observed among girls $(+0.087 \text{ kg/m}^2 \text{ vs. the unaffected areas, } P = 0.02)$ in Fukushima and both boys $(+0.165 \text{ kg/m}^2 \text{ sc})$ vs. the unaffected areas, P < 0.0001) and girls (+0.124 kg/m<sup>2</sup> vs. the unaffected areas, P =0.002) in Iwate. Nineteen months after the earthquake, increased BMIs were detected among boys (+0.137 kg/m<sup>2</sup> vs. the unaffected areas, P = 0.0003) and girls (+0.200 kg/m<sup>2</sup> vs. the unaffected areas, P < 0.0001) in Fukushima, whereas prolonged decreases in BMI was observed among boys (-0.218 kg/m<sup>2</sup> vs. the unaffected areas, P < 0.0001) and girls (-0.082) kg/m<sup>2</sup> vs. the unaffected areas, P = 0.011) in Miyagi. **Conclusion:** These results suggest that in the affected prefectures, preschool children gained weight immediately after the earthquake. The longer term impact of the earthquake on early childhood growth was more variable among the affected prefectures, possibly as a result of different speeds of recovery.

# 62 Strengths and limitations of this study

- The study analysed a unique dataset on child body mass index before and after a disaster.
- The study establishes a reference group for comparison as children mature.
- The study was limited by the lack of information on past diet and physical activity.
- The cohort of affected participants included only those who did not relocate and not
- 67 those who died or relocated.

 $\mathbf{5}$

# 69 INTRODUCTION

The Great East Japan Earthquake of 2011, with a magnitude of 9.0,[1] was the fourth largest earthquake ever recorded and the largest in Japan.[2] This earthquake together with the subsequent tsunami[3] and the nuclear power plant accident in Fukushima[4] caused immense damage to the Pacific coast of northeastern Japan. [5] The disaster resulted in a significant human and property toll: 19,466 people were killed, 6,152 were injured, 124,663 houses were destroyed and 274,638 homes were damaged.[6] The tragedy also affected daily life in the region, disrupting the normal eating and exercise habits of the inhabitants of Fukushima, Miyagi and Iwate Prefectures (Figure 1).[7] Experts in child growth have been very concerned about the short-term and long-term detrimental health effects of the earthquake and associated events on young children.[8, 9] In particular, schoolteachers and local paediatricians have focused on assessing potential weight gain among the children, since the affected children mainly consumed high-carbohydrate diets after the earthquake and were not allowed to play outdoors to avoid exposure to radiation from the damaged nuclear power plant.[10] Despite this warning about potential child obesity, there have been no reliable analyses on children's body weight since the earthquake. In addition, to the best of our knowledge, no study has investigated weight changes among resident children affected by other large natural disasters. The present study was driven by the question of whether the body mass indices (BMIs) of affected children had changed relative to the BMIs of comparable but unaffected children. Additionally, this report compared the prevalence of overweight children between affected and unaffected areas of Japan in an ecological study. 

91 METHODS

# 92 Study participants and measurements

93 On 27 August 2012, the Ministry of Health, Labour and Welfare of Japan sent a letter to

Yokomichi H et al.

94	nursery schools across Japan (some of which were undestroyed and still in operation in
95	affected prefectures) through domestic administrators requesting the recipients' participation
96	in the Nationwide Nursery School Survey on Child Health.[11] Nursery school records on
97	student height and weight in the affected and unaffected areas of northeastern Japan were
98	collected for the participating children born between 2 April 2006 and 1 April 2007 (Japanese
99	fiscal year 2006). Thus, the children evaluated were 4–5 years old during the month of the
100	first primary outcome evaluation (April 2011) and were 6–7 years old when data collection
101	was completed in 2013. Participating children were weighed in their underwear and without
102	shoes. Measurements were based on weight scales and stadiometres, which are legally
103	required equipment at all Japanese nursery schools and kindergartens that undergo half-yearly
104	standardisation by certified measurers.[12] The children were assessed biannually in April
105	and October, and the nursery schoolteachers mailed the records on each child's height and
106	weight to the central agency. Accordingly, we defined the half-yearly time points as every
107	April and October from 2008 to 2012. Missing data included data for those children who
108	moved out of the areas or died and were not included in the analyses. Analyses of the
109	obtained longitudinal data were based on the assumption of missing at random.[13] BMI was
110	calculated as each child's weight in kilograms divided by the square of their height in metres.
111	
112	Comparison of BMI changes
113	First, to gain an overview of the trends in children's BMIs, we represented the mean BMIs of
114	children living in the affected prefectures facing the Pacific Ocean (i.e. the Fukushima,
115	Miyagi and Iwate Prefectures) and then separately the children living on the other side of
116	northeastern Japan in unaffected areas (i.e. the Yamagata, Akita and Aomori Prefectures)
117	according to a fixed-effects model that estimates chronological means.[13, 14] For the

118 representations, we separately generated 4 models with an explanatory variable of the time

# **BMJ Open**

Yokomichi H et al.

119	points for the 3 affected prefectures and the pooled unaffected areas. According to the
120	estimated coefficients, we graphically plotted the mean BMIs for the affected prefectures and
121	the unaffected areas. Second, for the primary comparisons of interest using a retrospective
122	cohort design, we compared the BMI changes separately among the children from affected vs.
123	unaffected prefectures. The BMI changes after the earthquake were evaluated from a
124	reference baseline time point of October 2010, the last measured time point prior to the date
125	of the earthquake (11 March 2011), through April 2011, October 2011, April 2012 and
126	October 2012. We compared the BMI changes for children in each affected prefecture with
127	those of the unaffected areas in a single fixed-effects model,[14] a type of linear
128	mixed-effects model that is useful for analysis of longitudinal data.[13] A binary explanatory
129	variable was set for whether children lived in an affected or unaffected area, and the analyses
130	were adjusted using a covariate of age in month. The following fixed-effects model was
131	employed:
132	$BMI_{ijk} = (Time point)_i + (Time point*Area group)_{ij} + (Age in month)_k + \varepsilon_{ijk}$
133	$\varepsilon_{ijk} \sim N(0, \sigma^2)$
134	where <i>i</i> represents index time points of October 2010, April 2011, October 2011, April 2012
135	or October 2012; $j$ represents indices for each affected prefecture or unaffected area; and $k$
136	represents indices for individuals. (Time point) <sub>i</sub> equals zero when i equals October 2010 (the
137	reference baseline time point). (Time point*Area group) <sub>ij</sub> represents for an interaction term
138	between (Time point) <sub>i</sub> and (Area group) <sub>j</sub> , and equals zero at any time points when j equals
139	unaffected area. (Age in month) <sub>k</sub> is a covariate of adjustment for child age. $\varepsilon_{ijk}$ represents the
140	random effect of the error term in the model.
141	Consequently, we applied 3 models for comparison of BMI changes within the 3 affected
142	prefectures with a single reference for the unaffected areas. According to the coefficients in
143	the model, we also graphically plotted the BMI changes and then statistically evaluated the

	Yokomichi H et al.
144	differences in BMI change between each affected prefecture and the unaffected areas with the
145	statistical significance of the interaction term. All statistical analyses were performed with
146	sex stratification using SAS statistical software (version 9.4, SAS Institute, Cary, NC, USA).
147	Descriptive statistics are reported as means and standard deviations (SDs)/standard errors
148	(SEs). All reported <i>P</i> values are from 2-sided analyses, with <i>P</i> values <0.05 considered
149	statistically significant.
150	
151	Comparison in the prevalence of overweight children
152	For the secondary comparisons in an ecological study design, the prevalence of overweight
153	boys and girls in Fukushima, Miyagi and Iwate Prefectures and throughout Japan were
154	assessed for 6–17-year-old children attending primary, junior high and high schools using the
155	descriptive data provided through the School Health Statistics Research of Japan.[15] The
156	investigation by the School Health Statistics Research, which selects examined schools in a
157	stratified random sampling under Japanese law, [16] is conducted annually from April to June.
158	Because of widespread school dysfunction immediately after the disaster in March 2011, the
159	examination could not be conducted in the 3 affected prefectures in 2011. Therefore, we
160	compared the prevalence of overweight children from the 2012 examination with the

- prevalence from the 2010 examination for the 3 prefectures and across Japan to determine
- whether or not the prevalence had increased after the earthquake. The sources for nation-wide
- data comprised 4.8% of all Japanese schoolchildren in 2010 and 4.9% in 2012. In both 2010
  - and 2012, 270,720 primary school children aged 6-11 years, 225,600 junior high school
- students aged 12-14 years and 126,900 high school students aged 15-17 years were included.
- With these data, the definition of being overweight was weighing 20% or greater than a
- standard weight, where percent overweight = (measured weight – standard weight)  $\times$
- 100/standard weight for each given age, sex and height in accordance with the guidelines of

# **BMJ Open**

	Yokomichi H et al.
169	The Japanese Society for Pediatric Endocrinology.[17, 18] Because the source data were
170	based on the prevalence of this definition of being overweight, the definitions of overweight
171	children from the International Obesity Task Force[19] and the World Health
172	Organization[20] could not be used. Owing to the nature of the source data, tests of statistical
173	significance were not performed.
174	
175	RESULTS
176	Comparison of BMI changes
177	For the affected participants, data were collected from 646 boys and 597 girls that attended
178	97 nursery schools in Fukushima (nursery school participation rate [NPR], 31%); 904 boys
179	and 854 girls from 132 nursery schools in Miyagi (NPR, 38%) and 483 boys and 458 girls
180	from 81 nursery schools in Iwate (NPR, 23%). For the unaffected participants, we collected
181	data from 307 boys and 285 girls attending 42 nursery schools in Yamagata (NPR, 17%); 762
182	boys and 739 girls from 88 nursery schools in Akita (NPR, 35%) and 638 boys and 634 girls
183	from 108 nursery schools in Aomori (NPR, 23%).
184	Table 1 shows the baseline anthropometrics in October 2010. The mean age in the affected
185	and unaffected areas was 4.1 (SD, 0.3) years for boys and girls. The mean BMI in the
186	affected areas was 15.7 (SD, 1.2) kg/m <sup>2</sup> for boys and 15.6 (SD, 1.3) kg/m <sup>2</sup> for girls. In the
187	unaffected areas, the mean BMI was 15.6 (SD, 1.2) kg/m <sup>2</sup> and 15.6 (SD, 1.3) kg/m <sup>2</sup> for boys
188	and girls, respectively.

**Table 1** Baseline characteristics of participating boys and girls in October 2010 in northeast

191 Japan

Anthropometric	Affected areas		Unaffect	ted areas
measurements	Boys (n =	Girls (n =	Boys (n =	Girls (n =
	2033)	1909)	1707)	1658)
Age, years	4.1 (0.3)	4.1 (0.3)	4.1 (0.3)	4.1 (0.3)
Height, cm	100.6 (4.3)	99.6 (4.1)	100.8 (4.2)	100.0 (4.2)
Weight, kg	15.9 (2.0)	15.5 (1.9)	16.0 (1.9)	15.6 (2.0)
Body mass index,		15 ( (1 2)	15 ( (1 0)	15 ( (1 0)
kg/m <sup>2</sup>	15.7 (1.2)	15.6 (1.3)	15.6 (1.2)	15.6 (1.3)

192 All values are presented as mean (standard deviation).

Figure 2 and Supplementary Table 1 present the estimated BMIs from April 2008 to October 2012 graphically and numerically, respectively. For the primary cohort-design comparisons, Figure 3 and Supplementary Table 2 illustrate the estimated changes in BMI from October 2010 to October 2012 graphically and numerically, respectively, for children residing in each affected prefecture in comparison with those residing in the unaffected areas. Compared to the unaffected areas, BMI observed in the Fukushima Prefecture was significantly higher among boys in October 2012 (+0.137 kg/m<sup>2</sup>, P = 0.0003) and among girls in April 2011 (+0.087 kg/m<sup>2</sup>, P = 0.02), April 2012 (+0.122 kg/m<sup>2</sup>, P = 0.0013) and October 2012 (+0.200 kg/m<sup>2</sup>, P < 0.0001). Compared to the unaffected areas, BMI observed in the Miyagi Prefecture was significantly lower among boys in October 2011 ( $-0.076 \text{ kg/m}^2$ , P = 0.02), April 2012  $(-0.165 \text{ kg/m}^2, P < 0.0001)$  and October 2012  $(-0.218 \text{ kg/m}^2, P < 0.0001)$  and among girls in October 2012 ( $-0.082 \text{ kg/m}^2$ , P = 0.011). 

# BMJ Open

Yokomichi H et al.

207 Compared to the unaffected areas, BMI observed in the Iwate Prefecture was significantly 208 higher among boys in April 2011 (+0.165 kg/m<sup>2</sup>, P < 0.0001) and among girls in April 2011 209 (+0.124 kg/m<sup>2</sup>, P = 0.002).

211 Comparison of the prevalence of overweight children

The secondary ecological study compared the prevalence of overweight boys and girls in Fukushima, Miyagi and Iwate Prefectures as well as across Japan in both 2010 and 2012 (Figure 4). We observed increases in the prevalence of overweight individuals among primary school boys in the 6-11 age group in Fukushima, the 6-12 age group in Miyagi, the 6-9 age group in Iwate and the 6-10 age group across Japan. We also found increases in the prevalence of overweight primary school girls in the 6-10 age group in Fukushima, the 8-11age group in Miyagi and the 6-11 age group across Japan. Among the girls aged 6-7 years in Miyagi, we also observed a slightly decreased prevalence of overweight children. No noteworthy change in the prevalence of overweight children was observed among primary school girls (6–12 years) in Iwate. In the 3 affected prefectures and across Japan, there were no consistent trends in the prevalence of overweight individuals among junior high and high school students aged 12-17 years.

**DISCUSSION** 

226 Main results

227 Our data on post-disaster BMI changes (Figure 3) showed immediate increases in BMI 228 among the preschool boys and girls residing in each affected prefecture, as if in response to Yokomichi H et al.

229	the disaster in March 2011. In addition, there was evidence of a prolonged increase in BMI
230	among the boys and girls residing in Fukushima. On the other hand, in Miyagi, we identified
231	a trend of immediate weight gain with subsequent weight loss in both boys and girls. In Iwate,
232	the BMIs of boys and girls gradually approached those of the children living in unaffected
233	areas. In the ecological study (Figure 4), there were increases from 2010 to 2012 in the
234	prevalence of overweight boys and girls in Fukushima and overweight boys in Miyagi and
235	Iwate in their early primary school years, although the results were inconsistent among girls
236	in Miyagi and Iwate that were also in early primary school. Although the psychological harm
237	that natural disasters cause to children has been reported, [21] the present results have
238	provided additional evidence of an immediate and potentially prolonged increase in BMI
239	among young children following a major disaster.

# **Possible explanations**

At the time of the 2011 earthquake, electricity, gas lines, water supply lines, sewage systems, railways and traffic transportation were all interrupted.[5] The interruption in daily transportation resulted in severe shortages of meat, fish, egg and vegetables.[22] As typically occurs with disasters, administrative and non-political/non-profit organisations supplied carbohydrates such as rice balls and bread to affected populations. [8, 23] In the 3 affected prefectures, the priority was to supply meals to the affected children. [24] The affected children are presumed to have gained weight due to the carbohydrate-based diet that was supplied, which may account for the weight gain observed in boys and girls in 3 prefectures immediately after the earthquake, either with or without statistical significance (Figure 3). Furthermore, school gymnasiums were used as shelters for residents, and school playgrounds were opened for provisional housing at that time.[23] In Fukushima, where the nuclear power  Page 15 of 44

# **BMJ Open**

Yokomichi H et al.

253	plant station experienced hydrogen explosions, there were few chances to play outside due to
254	fear of radiation exposure, the lack of available playgrounds and an overall mournful mood
255	among the population. Additionally, on 19 April 2011, the Ministry of Education, Culture,
256	Sports, Science and Technology of Japan issued a notice to all schools in Fukushima that
257	principals needed to restrict the availability of school buildings and playgrounds as long as
258	the schools were exposed to 1 mSv or more of radiation per year.[25] The limited outdoor
259	activity may have been reflected in the prolonged BMI increases observed among children
260	living in Fukushima. In contrast, in Miyagi, city infrastructure, hospitals, school education
261	and corporate activities have been recovering much sooner than in Fukushima.[26, 27] This
262	contrast may in part explain the different trends in weight loss observed among boys and girls
263	living in Miyagi. However, how they lost weight has not been established. In Iwate, one
264	report has described a worsening of the mean plasma glucose and haemoglobin A1c levels in
265	63 affected patients with diabetes from 109.4 mg/dL (SE, 3.9, 6.08 mmol/L [SE, 0.22]) to
266	134.3 mg/dL (SE, 7.2, 7.46 mmol/L [SE, 0.40]) and from 5.9 % (SE, 0.2, 6.8 mmol/L [SE,
267	0.3]) to 6.5 % (SE, 0.2, 7.8 mmol/L [SE, 0.3]), respectively, 4 months after the
268	earthquake.[28] The authors were physicians in charge of following up with these patients
269	and they witnessed unbalanced diets heavy with sweets, canned products and boil-in-the-bag
270	foods provided to the evacuees. The authors have speculated that the worsening of the
271	glycaemic control was partly due to unbalanced diets. As was the case in Fukushima and
272	Miyagi, the reported situation of limited access to an adequate diet in Iwate may partly
273	explain the immediate BMI increases observed among preschool boys and girls after the
274	earthquake. Because the Iwate Prefecture is relatively far from the epicentre of the earthquake
275	and the damaged nuclear power plant, the daily lives of its inhabitants may have returned to
276	normal sooner than it did for those in Fukushima.[26, 27]

 BMJ Open: first published as 10.1136/bmjopen-2015-010978 on 7 April 2016. Downloaded from http://bmjopen.bmj.com/ on June 5, 2025 at Department GEZ-LTA Erasmushogeschool

Extraordinary experiences during major disasters change the lives of inhabitants and lead to

an array of physical and mental problems.[29-31] A study from medical examinations has

shown a +0.2–0.3 BMI change in a year among Fukushima evacuees.[32] Another report

from a cohort in Miyagi has described a  $+0.25 \text{ kg/m}^2$  BMI change among city officials

population in 2011 after adjusting for sex and age.[33] Our results comparing children in

Fukushima and Miyagi are consistent with these previous reports that investigated changes

among adults. As described above, the observed BMI increases immediately after the disaster

magnitude on the Richter scale), physicians have also reported worsened glycaemic controls

among diabetic patients. [34] The authors, who were members of disaster relief teams, have

explained that the exacerbations were partly due to unhealthy high-carbohydrate diets and

overeating, in responses to sleeplessness and a fear of hunger. At the 2004 Mid-Niigata

earthquake (6.8 magnitude on the Richter scale), a report from health check-up data for

overworked male prefectural governmental staff members has described an average +0.2

 $kg/m^2$  yearly BMI increase among victims and an average +0.1 kg/m<sup>2</sup> yearly BMI increase

a study has reported that increased sympathetic hormone levels of leptin and cortisol

and cortisol is induced by psychological stress,[38] hormonal changes in hypervigilant

among non-victims.[35] At the 1999 Taiwan earthquake (7.2 magnitude on the Richter scale),

associated with hyperarousal.[36] Because leptin regulates food intake and body weight,[37]

individuals following major earthquakes may cause disturbances in their appetite and BMI.

engaging in post-quake recovery and a  $-0.09 \text{ kg/m}^2$  BMI change among the general

may be partly attributed to unbalanced diet and elevated hormone levels induced by

psychological stresses. At the 1995 Great Hanshin (Kobe) earthquake in Japan (7.3

# **Practical implications**

Medical attention pertaining to mental health and life-style-related issues must be provided adults and in particular elderly adults with a chronic condition during earthquake recovery.[39] With most natural disasters, the focus has been traditionally placed mainly on the health problems of adults and not on the needs of children. This study sheds new light on the risks that a disaster can pose to childhood growth and their risk of obesity after a disaster. The mean BMI levels among male children in Fukushima and male and female children in Iwate, all approximately 4 years old at the time that the earthquake struck, appear to show a relatively earlier adiposity rebound, with both immediate and prolonged weight gain (Figure 2). In paediatrics, adiposity rebound is defined as the point of the minimal BMI that comes at 5-6 years old on average. [40] There is a consensus that early adiposity rebound predicts diabetes and obesity in adulthood, [41, 42] although discussion continues about whether the reason for undesirable outcomes at adult age is due to children's lifestyles, [43] to their foetal lives[44] or to other causal mechanisms.[45] Hence, if earlier adiposity rebound indeed occurs in a subset of children after natural disasters due to lack of diet and exercise, administrative agencies and local paediatricians should pre-emptively address this source of future cardiovascular diseases. Because being physically active during the preschool ages reduces BMI over a long term, [46] in the immediate aftermath of an earthquake, play space availability should be ensured, balanced diets should be supplied, and schools should be reopened at the earliest possible date. Additionally, endocrinological and metabolic abnormalities often appear in preschool children with a 12-month history of being overweight.[47] Indeed, stress experienced in early childhood can persist and cause future neurologic and endocrine-related cardiovascular disease.[48] Thus, paediatricians need to assure long term follow-up and pay close attention to the health of children affected by a disaster.

# 328 Limitations and strengths

The present study had several limitations. First, the lack of information on diet and physical activity may limit the comparability of outcomes between the affected and unaffected areas studied. Because the Pacific side of northeastern Japan receives less snow than the opposite side, exercise may be more frequent in the affected areas than in the unaffected areas. This cultural factor may induce bias toward decreasing BMIs of the affected children residing on the Pacific Ocean side. Considering this negative bias in BMI, the weight gains among children living in Fukushima and Iwate might be larger, and the weight loss observed in Miyagi might be smaller than thought. To correct for this potential bias, study initiation with a matching method based on cultural confounders for a quasi-experimental design might have reduced the bias. Even so, we minimised the bias by selecting an unaffected reference group from the northeastern region of Japan, where the diet was considered to be similar to that in the three affected prefectures. [49] Second, the results were limited with no use of z score (standard deviation score) for BMI,[50-52] which might have more properly adjusted for age. Although the standardisation by z score may be ideal for comparison of raw BMI values, the need for comparison of the BMI changes did not allow us to use the standardisation. Thus, we chose instead to compare BMI changes between two groups and make the simple adjustment of a covariate for child age in month in the model. A third limitation was the representativeness of the sample population in affected areas of northeastern Japan. The registered children for available data attended nursery schools that responded to the request letter. Therefore, the data did not include children who died, children in ruined or dysfunctional nursery schools without schoolteachers or children who had moved away from the area. Because there is no data on whether those most affected children gained or lost

Page 19 of 44

# **BMJ Open**

weight, the direction and the amount of this bias in BMI has not been determined. Conversely,
the study design could have specifically focused on children that experienced severe suffering.
Because in the study design, the definition of 'affected' children did not identify those who
were evacuated to provisional houses or who were physically impacted by the tsunami, the
observed influence of the disaster on child growth may have been reduced.

The assembled longitudinal data would be strengthened by its uniqueness in recording child growth before and after a disaster. Although medical attention to the physical and mental health of people affected by a disaster has recently increased, surveys pertaining to this particular disaster have just begun. [53] A number of studies originating from these surveys should provide evidence to bolster disaster medicine. Another strength of this study is comparison of affected children with the unaffected children, who were considered to have been normally growing. For example, although one report described the health status of Iraqi refugees before immigration to the U.S. with an obesity prevalence of 24.6% and a hypertension prevalence of 15.2% [54] the lack of information on unaffected Iragis prevented an estimation of the influence of refugee life on human health. Similarly, the impact of a study that reported a high prevalence of mental disorders in Iraqi children during a war, [55] would be weakened because of the lack an unexposed comparator reference group. The evaluation of BMIs in growing children is usually difficult. However, we believe that an epidemiological answer has been provided to the study question on whether children's BMIs were influenced by the disaster. Furthermore, the phenomenon of an increased prevalence of overweight early-year primary school children in Fukushima has been observed in the ecological study. Although an ecological fallacy may exist, it is interesting that this phenomenon has appeared in Fukushima, where there are reports of delayed reconstruction.

#### Conclusion

376	The data from earthquake-stricken northeastern Japan have shown an immediate increase in
377	BMI among children living in three affected prefectures. The data have also indicated trends
378	of prolonged BMI increases among children in Fukushima and prolonged BMI decreases
379	among children in Miyagi. These data emphasise the need for attention to and follow-up for
380	affected children after a natural disaster to prevent undesirable health outcomes.
380	affected children after a natural disaster to prevent undesirable health outcomes.

Prevalence of overweight children in Fukushima, Miyagi and Iwate Prefectures and throughout Japan in 2010 versus 2012 from the School Health Statistics Research of Japan. The term 'overweight' was defined as weighing 20% or more than standard weight in accordance with the guidelines of The Japanese Society for Pediatric Endocrinology.

### STROBE Statement-checklist of items that should be included in reports of observational studies

	Item No.	Recommendation	Page No.	Relevant text from manuscript
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	3	Line 39
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	3	Line 37–59
Introduction				
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	6	Line 77–86
Objectives	3	State specific objectives, including any prespecified hypotheses	6	Line 86-89
Methods				
Study design	4	Present key elements of study design early in the paper	8	Line 121–123
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure,		
		follow-up, and data collection	6–7	Line 93–96, 113–117
Participants	6	<ul> <li>(a) Cohort study—Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up</li> <li><i>Case-control study</i>—Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls</li> <li><i>Cross-sectional study</i>—Give the eligibility criteria, and the sources and methods of selection of participants</li> <li>(b) Cohort study—For matched studies, give matching criteria and number of exposed and unexposed</li> <li><i>Case-control study</i>—For matched studies, give matching criteria and the number of controls per case</li> </ul>	7	Line 96–99 NA
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	8	Line 126–130
Data sources/	8*	For each variable of interest, give sources of data and details of methods of assessment	~	
measurement		(measurement). Describe comparability of assessment methods if there is more than one group	8	Line 123–126
Bias	9	Describe any efforts to address potential sources of bias	8	Line 129–130
Study size	10	Explain how the study size was arrived at	9–10	Line 162–166 177–18

AT-LZE Townloaded from http://bmjopen.2013-0105 on 7 April 2016. Downloaded from http://bmjopen.bmj.com/ on June 5, 2025 at Department GEZ-LTA Erasmushogeschool Protected by copytighteing/fackgesig/ated interfaction/file/fackings and single from http://bmiopen.bm/

Quantitative	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which		
variables		groupings were chosen and why	8	Line 123–126
Statistical	12	(a) Describe all statistical methods, including those used to control for confounding	8, 17	Line 126–140, 339–34
methods		(b) Describe any methods used to examine subgroups and interactions	8	Line 132–139
		(c) Explain how missing data were addressed	7	Line 107–110
		(d) Cohort study—If applicable, explain how loss to follow-up was addressed		
		Case-control study-If applicable, explain how matching of cases and controls was addressed		
		Cross-sectional study—If applicable, describe analytical methods taking account of sampling		
		strategy		NA
		( <u>e</u> ) Describe any sensitivity analyses		NA
Results				
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible,		
		examined for eligibility, confirmed eligible, included in the study, completing follow-up, and	9–10	Line 162–166, 177–18
		analysed		
		(b) Give reasons for non-participation at each stage	6–7	Line 93–96
		(c) Consider use of a flow diagram		NA
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information		
		on exposures and potential confounders	11	Table 1
		(b) Indicate number of participants with missing data for each variable of interest		NA
		(c) Cohort study—Summarise follow-up time (eg, average and total amount)	8	Line 123–126
Outcome data	15*	Cohort study—Report numbers of outcome events or summary measures over time		
			Supplementary	Supplementary Table 1
		Case-control study—Report numbers in each exposure category, or summary measures of		NA
		exposure		
		Cross-sectional study—Report numbers of outcome events or summary measures		NA
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their		
		precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and		
		why they were included	11–12	Line 199–209
		(b) Report category boundaries when continuous variables were categorized	28 (Figure 4,	Line 553–554
			legend)	
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful		
		2		

ATJ-ZED insertion of the store of the store

		time period		NA
Continued on next page Other analyses	17	Report other analyses done-eg analyses of subgroups and interactions, and sensitivity analyses		NA
Discussion				
Key results	18	Summarise key results with reference to study objectives	12–13	Line 226–239
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss		
		both direction and magnitude of any potential bias	17–18	Line 328–354
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of		
		analyses, results from similar studies, and other relevant evidence	15	Line 278–300
Generalisability	21	Discuss the generalisability (external validity) of the study results	17–18	Line 344–354
Other information	on			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the		
		original study on which the present article is based	20	Line 390–395

\*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at http://www.plosmedicine.org/, Annals of Internal Medicine at http://www.annals.org/, and Epidemiology at http://www.epidem.com/). ## ABSTRACT index (BMI) of preschool children. Design: Retrospective cohort study and ecological study. northeast Japan. three affected prefectures and unaffected prefectures, respectively, all aged 3-4 years at the from the affected prefectures. evaluated post-disaster changes in the prevalence of overweight children. **Results:** One month after the earthquake, significantly increased BMIs were observed among boys, whereas Fukushima had slightly decreased prevalence of overweight girls, compared

**Objective:** To evaluate the impact of the 2011 great east Japan earthquake on body mass

Setting: Affected prefectures (Fukushima, Miyagi and Iwate) and unaffected prefectures in

Participants: The cohort study assessed 2033 and 1707 boys and 1909 and 1658 girls in

time of the earthquake. The ecological study examined random samples of school children

Primary and secondary outcome measures: The cohort study compared post-disaster

changes in BMIs and the prevalence of overweight and obese children. The ecological study

girls (+0.087 kg/m<sup>2</sup> vs. unaffected prefectures) in Fukushima and boys and girls (+0.165  $kg/m^2$  and +0.124 kg/m<sup>2</sup>, respectively vs. unaffected prefectures) in Iwate. Nineteen months after the earthquake, significantly increased BMIs were detected among boys and girls (+0.137 kg/m<sup>2</sup> and +0.200 kg/m<sup>2</sup>, respectively vs. unaffected prefectures) in Fukushima, whereas significantly decreased BMIs were observed among boys and girls (-0.218 kg/m<sup>2</sup>) and  $-0.082 \text{ kg/m}^2$ , respectively vs. unaffected prefectures) in Miyagi. One month after the earthquake, Fukushima, Miyagi and Iwate had slightly increased prevalence of overweight

with the unaffected prefectures. The ecological study detected increases in the prevalence of

overweight boys and girls in Fukushima who were 6–11 and 6–10 years of age, respectively.

#### **BMJ Open**

Yokomichi H et al.

- **Conclusion:** These results suggest that in the affected prefectures, preschool children gained
- 61 weight immediately after the earthquake. The long term impact of the earthquake on early
- 62 childhood growth was more variable among the affected prefectures, possibly as a result of
- 63 different speeds of recovery.
- - 65 Word count: 297 words

## 66 Strengths and limitations of this study

- The study analysed a unique dataset on child body mass index before and after a disaster.
- The study establishes a reference group for comparison as children mature.
- 69 The study data were limited to nursery school records.
- 70 The cohort of affected participants did not include those who died or relocated.
- The information on previous diets and physical activities was lacking.

#### 73 INTRODUCTION

The great east Japan earthquake of 2011, with a magnitude of 9.0,[1] was the fourth largest earthquake ever recorded and the largest in Japan.[2] This earthquake together with the subsequent tsunami[3] and the nuclear power plant accident in Fukushima[4] caused immense damage to the Pacific coast of northeast Japan.[5] The disaster resulted in a significant human and property toll: 19,466 people were killed, 6,152 were injured, 124,663 houses were destroyed and 274,638 homes were damaged.[6] The tragedy also affected daily life in the region, disrupting the normal eating and exercise habits of the inhabitants of Fukushima, Miyagi and Iwate prefectures (Figure 1).[7] Experts in child growth have been very concerned about the short- and long-term detrimental health effects of the earthquake and associated events on young children.[8, 9] In particular, schoolteachers and local paediatricians have focused on assessing potential weight gain among the children because the affected children mainly consumed high-carbohydrate diets after the earthquake and were not allowed to play outdoors to avoid exposure to radiation from the damaged nuclear power plant.[10] Despite this warning about potential child obesity, there have been no reliable analyses on children's body weight since the earthquake. In addition, to the best of our knowledge, no study has investigated weight changes among resident children affected by other large natural disasters. The present study was driven by the question of whether the body mass indices (BMIs) of the children in each affected prefecture had changed relative to the BMIs of comparable but unaffected children. Furthermore, this report compared the prevalence of overweight and obese children between affected and unaffected areas in a cohort and an ecological designs.

#### 96 METHODS

#### 97 Study participants and measurements

Yokomichi H et al.

98	On 27 August 2012, the Ministry of Health, Labour and Welfare of Japan sent a letter to
99	nursery schools across Japan (some of which were undestroyed and still in operation in
100	affected prefectures) through domestic administrators requesting the recipients' participation
101	in the Nationwide Nursery School Survey on Child Health.[11] Nursery school records on
102	student height and weight in the affected and unaffected prefectures of northeast Japan were
103	collected for the participating children born between 2 April 2006 and 1 April 2007 (Japanese
104	fiscal year 2006). Thus, the children evaluated were 4–5 years old during the month of the
105	first primary outcome evaluation (April 2011) and were 6–7 years old when data collection
106	was completed in 2013. Participating children were weighed in their underwear and without
107	shoes. Measurements were based on weight scales and stadiometres, which are legally
108	required equipment at all Japanese nursery schools and kindergartens that undergo half-yearly
109	standardisation by certified measurers.[12] The children were biannually assessed in April
110	and October, and the nursery schoolteachers mailed the records on each child's height and
111	weight to Tohoku University. Accordingly, we defined the half-yearly time points as every
112	April and October from 2008 to 2012. The study participants were children who attended
113	nursery schools that responded to the letter of request. Missing data included that for children
114	who did not attend the participating nursery schools, moved out of the prefectures or died.
115	Because there are no published data of year 2011 for the exact number of the children born in
116	fiscal year 2006 in each prefecture, the approximate proportion of participants among the
117	resident children was calculated according to the number of the first grade primary school
118	students in fiscal year 2012.[13]

120 Comparison of BMI changes

First, to gain an overview of the trends in children's BMIs, we represented the mean BMIs of children living in the affected prefectures facing the Pacific Ocean (i.e. Fukushima, Miyagi

#### **BMJ Open**

Yokomichi H et al.

123	and Iwate prefectures) and then separately the children living on the other side of northeast
124	Japan in unaffected prefectures (i.e. Yamagata, Akita and Aomori prefectures) according to a
125	fixed-effects model that estimates chronological means.[14, 15] For the representations, we
126	separately generated 4 models with an explanatory variable of the time points for the three
127	affected prefectures and the pooled unaffected prefectures. According to the estimated
128	coefficients, we graphically plotted the mean BMIs for the affected prefectures and the
129	unaffected prefectures. Second, for the primary comparisons of interest using a retrospective
130	cohort design, we compared the BMI changes among the children from affected versus
131	unaffected prefectures. Because of the difficulty in comparing BMIs of growing children
132	between different areas, the BMI changes after the earthquake were evaluated from a
133	reference baseline time point of October 2010, the last measured time point prior to the date
134	of the earthquake (11 March 2011), through April 2011, October 2011, April 2012 and
135	October 2012. We compared the BMI changes of children in each affected prefecture with
136	those in the unaffected prefectures using a repeated-measures ANOVA model for mean
137	changes from baseline[16] (diff BMI) for a difference-in-difference analysis of longitudinal
138	data.[15] A binary explanatory variable was set for whether children lived in an affected or
139	unaffected area, and the analyses were adjusted using a covariate of age in month. The
140	following fixed-effects model was employed:
141	<i>diff BMI</i> <sub>ijk</sub> = (Time point) <sub>i</sub> + (Time point*Area group) <sub>ij</sub> + (Age in month) <sub>k</sub> + $\varepsilon_{ijk}$
142	$\varepsilon_{ijk} \sim N(0, \sigma^2)$
143	where <i>i</i> represents index time points of October 2010, April 2011, October 2011, April 2012
144	or October 2012; <i>j</i> represents indices for each affected prefecture or unaffected area; and <i>k</i>
145	represents indices for individuals. (Time point) <sub>i</sub> equals zero when i equals October 2010 (the
146	reference baseline time point). (Time point*Area group) <sub>ij</sub> represents for an interaction term
147	between (Time point) <sub>i</sub> and (Area group) <sub>j</sub> , and equals zero at any time points when j equals

BMJ Open: first published as 10.1136/bmjopen-2015-010978 on 7 April 2016. Downloaded from http://bmjopen.bmj.com/ on June 5, 2025 at Department GEZ-LTA Erasmushogeschool

Yokomichi H et al.

148	unaffected area. (Age in month) <sub>k</sub> is a covariate of adjustment for child age. $\epsilon_{ijk}$ represents the
149	random effect of the error term in the model.
150	Consequently, we applied three models for comparison of BMI changes within the three
151	affected prefectures with a single reference for the unaffected prefectures. According to the
152	coefficients in the model, we also graphically plotted the BMI changes and then statistically
153	evaluated the differences in BMI change between each affected prefecture and the unaffected
154	prefectures with the statistical significance of the interaction term. All statistical analyses
155	were performed with sex stratification using SAS statistical software (version 9.4, SAS
156	Institute, Cary, NC, USA). Descriptive statistics are reported as means and standard
157	deviations (SDs)/standard errors (SEs). All reported P values are from 2-sided analyses, with
158	P values <0.05 considered statistically significant.

Yokomichi H et al.

In addition, for an ecological study design, the prevalence of overweight boys and girls in the affected prefectures and throughout Japan were assessed for 6–17-year-old children attending primary, junior high and high schools using the descriptive data provided through the School Health Statistics Research of Japan. [18] The investigation by the School Health Statistics Research, which selects examined schools in a stratified random sampling under Japanese law,[19] is conducted annually from April to June. Because of widespread school dysfunction immediately after the disaster in March 2011, the examination could not be conducted in the three affected prefectures in 2011. Therefore, we compared the prevalence of overweight children from the 2012 examination with the prevalence from the 2010 examination for the three prefectures and across Japan to determine whether or not the prevalence had increased after the earthquake. The sources for nation-wide data comprised 4.8% of all Japanese schoolchildren in 2010 and 4.9% in 2012. In both 2010 and 2012, 270,720 primary school children aged 6–11 years, 225,600 junior high school students aged 12–14 years and 126,900 high school students aged 15–17 years were included. With these data, the definition of being overweight was weighing 20% or greater than a standard weight, where percent overweight =(measured weight – standard weight)  $\times$  100/standard weight for each given age, sex and height in accordance with the guidelines of The Japanese Society for Pediatric Endocrinology.[20, 21] RESULTS **Comparison of BMI changes** The data for the affected children on approximately 8.8% of resident children were collected

223	was significantly lower among boys in October 2011 (-0.076 kg/m <sup>2</sup> , P=0.018), April 2012
224	(-0.165 kg/m <sup>2</sup> , P<0.0001) and October 2012 (-0.218 kg/m <sup>2</sup> , P<0.0001) and among girls in
225	October 2012 (-0.082 kg/m <sup>2</sup> , <i>P</i> =0.011).

Compared to the unaffected prefectures, the observed change in BMI in Iwate prefecture was significantly higher among boys in April 2011 (+0.165 kg/m<sup>2</sup>, P<0.0001) and among girls in April 2011 (+0.124 kg/m<sup>2</sup>, P=0.0019).

#### 230 Comparison of the prevalence of overweight and obese children

Figure 4 shows the secondary comparisons of the prevalence of overweight and obese children in Fukushima, Miyagi and Iwate prefectures with the pooled population of the unaffected prefectures. Compared with the unaffected prefectures, there was a slight increase in the changes of the prevalence of overweight boys between October 2010 and April 2011 residing in Fukushima, Miyagi and Iwate. In contrast, there was a slight decrease in the change of the prevalence of overweight girls residing in Fukushima. Compared with the unaffected prefectures, a slight increase in the changes of the prevalence of obese individuals between October 2010 and April 2011 was observed among boys in Iwate and among girls in Fukushima, Miyagi and Iwate. In contrast, a slight decrease in the change of the prevalence of obese boys was observed in Miyagi. The ecological study also compared the prevalence of overweight children in the affected prefectures as well as across Japan in both 2010 and 2012 (Supplementary Figure 1). We observed increases in the prevalence of overweight individuals among primary school boys in the 6–11 age group in Fukushima, the 6–12 age group in Miyagi, the 6-9 age group in Iwate and the 6-10 age group across Japan. We also found increases in the prevalence of overweight primary school girls in the 6–10 age group in Fukushima, the 8-11 age group in Miyagi and the 6-11 age group across Japan. Among the  Yokomichi H et al.

247	girls aged 6-7 years in Miyagi, we also observed a slightly decreased prevalence of
248	overweight children. No noteworthy change in the prevalence of overweight children was
249	observed among primary school girls (6-12 years) in Iwate. In the three affected prefectures
250	and across Japan, there were no consistent trends in the prevalence of overweight individuals
251	among junior high and high school students aged 12–17 years.

#### DISCUSSION

#### Main results

Our data on post-disaster BMI changes (Figure 3) showed immediate increases in BMI among the preschool boys and girls residing in each affected prefecture, as if in response to the disaster in March 2011. In addition, there was evidence of a prolonged increase in BMI among the boys and girls residing in Fukushima. On the other hand, in Miyagi, we identified a trend of immediate weight gain with subsequent weight loss in both boys and girls. In Iwate, the BMIs of boys and girls gradually approached those of the children living in unaffected prefectures. The prevalence of obese individuals in the cohort data increased to one month after the earthquake among boys in Iwate and among girls in the three affected prefectures, compared with that in the unaffected prefectures (Figure 4). In the ecological study (Supplementary Figure 1), there were increases from 2010 to 2012 in the prevalence of overweight boys and girls in Fukushima and overweight boys in Miyagi and Iwate in their early primary school years, although the results were inconsistent among girls in Miyagi and Iwate that were also in early primary school years. Although the psychological harm that natural disasters cause to children has been reported, [22] the present results have provided additional evidence of an immediate and potentially prolonged increase in BMI among young

Yokomichi H et al.

children following a major disaster.

#### **Possible explanations**

At the time of the 2011 earthquake, electricity, gas lines, water supply lines, sewage systems, railways and traffic transportation were all interrupted.[5] The interruption in daily transportation resulted in severe shortages of meat, fish, egg and vegetables.[23] As typically occurs with disasters, administrative and non-political/non-profit organisations supplied carbohydrates such as rice balls and bread to affected populations. [8, 24] In the three affected prefectures, the priority was to supply meals to the affected children. [25] The affected children are presumed to have gained weight due to the carbohydrate-based diet that was supplied, which may account for the weight gain observed in boys and girls in the three affected prefectures immediately after the earthquake, either with or without statistical significance (Figure 3). Furthermore, school gymnasiums were used as shelters for evacuees, and school playgrounds were opened for provisional housing at that time.[24] In Fukushima, where the nuclear power plant station experienced hydrogen explosions, there were few chances to play outside due to fear of radiation exposure, the lack of available playgrounds and an overall mournful mood among the population. Additionally, on 19 April 2011, the Ministry of Education, Culture, Sports, Science and Technology of Japan issued a notice to all schools in Fukushima that principals needed to restrict the availability of school buildings and playgrounds as long as the schools were exposed to 1 mSv or more of radiation per year.[26] The limited outdoor activity may have been reflected in the prolonged BMI increases observed among children living in Fukushima. In contrast, in Miyagi, city infrastructure, hospitals, school education and corporate activities have been recovering much sooner than in Fukushima. [27, 28] This contrast may in part explain the different trends in  Yokomichi H et al.

294	weight loss observed among boys and girls living in Miyagi. However, how they lost weight
295	has not been established. In Iwate, one report has described a worsening of the mean plasma
296	glucose and haemoglobin A1c levels in 63 affected patients with diabetes from 109.4 mg/dL
297	(SE, 3.9, 6.08 mmol/L [SE, 0.22]) to 134.3 mg/dL (SE, 7.2, 7.46 mmol/L [SE, 0.40]) and
298	from 5.9 % (SE, 0.2, 6.8 mmol/L [SE, 0.3]) to 6.5 % (SE, 0.2, 7.8 mmol/L [SE, 0.3]),
299	respectively, 4 months after the earthquake.[29] The authors were physicians in charge of
300	following up with these patients and they witnessed unbalanced diets heavy with sweets,
301	canned products and boil-in-the-bag foods provided to the evacuees. The authors have
302	speculated that the worsening of the glycaemic control was partly due to unbalanced diets. As
303	was the case in Fukushima and Miyagi, the reported situation of limited access to an adequate
304	diet in Iwate may partly explain the immediate BMI increases observed among preschool
305	boys and girls after the earthquake. Because Iwate prefecture is relatively far from the
306	epicentre of the earthquake and the damaged nuclear power plant (Figure 1), the daily lives of
307	its inhabitants may have returned to normal sooner than it did for those in Fukushima.[27, 28]
308	
309	Comparison with previous studies

#### **Comparison with previous studies**

Extraordinary experiences during major disasters change the lives of inhabitants and lead to an array of physical and mental problems.[30-32] A study from medical examinations has shown a +0.2–0.3 BMI change in a year among Fukushima evacuees.[33] Another report from a cohort in Miyagi has described a  $+0.25 \text{ kg/m}^2$  BMI change among city officials engaging in post-quake recovery and a  $-0.09 \text{ kg/m}^2$  BMI change among the general population in 2011 after adjusting for sex and age.[34] Our results comparing children in Fukushima and Miyagi are consistent with these previous reports that investigated changes among adults. As described above, the observed BMI increases immediately after the disaster 

#### **BMJ Open**

Yokomichi H et al.

318	may be partly attributed to unbalanced diet and elevated hormone levels induced by
319	psychological stresses. At the 1995 Great Hanshin (Kobe) earthquake in Japan (7.3
320	magnitude on the Richter scale), physicians have also reported worsened glycaemic controls
321	among diabetic patients.[35] The authors, who were members of disaster relief teams, have
322	explained that the exacerbations were partly due to unhealthy high-carbohydrate diets and
323	overeating, in responses to sleeplessness and a fear of hunger. At the 2004 Mid-Niigata
324	earthquake (6.8 magnitude on the Richter scale), a report from health check-up data for
325	overworked male prefectural governmental staff members has described an average +0.2
326	kg/m <sup>2</sup> yearly BMI increase among victims and an average $+0.1$ kg/m <sup>2</sup> yearly BMI increase
327	among non-victims.[36] At the 1999 Taiwan earthquake (7.2 magnitude on the Richter scale),
328	a study reported that increased sympathetic hormone levels of leptin and cortisol associated
329	with hyperarousal.[37] Because leptin regulates food intake and body weight,[38] and
330	cortisol is induced by psychological stress,[39] hormonal changes in hypervigilant
331	individuals following major earthquakes may cause disturbances in their appetite and BMI.

#### **Practical implications**

Medical attention pertaining to mental health and life-style-related issues must be provided adults and in particular elderly adults with a chronic condition during earthquake recovery.[40] With most natural disasters, the focus has been traditionally placed mainly on the health problems of adults and not on the needs of children. This study sheds new light on the risks that a disaster can pose to childhood growth and their risk of obesity after a disaster. The mean BMI levels among boys in Fukushima and boys and girls in Iwate, all approximately four years old at the time that the earthquake struck, appear to show a relatively earlier adiposity rebound, with both immediate and prolonged weight gain (Figure  Yokomichi H et al.

2). In paediatrics, adiposity rebound is defined as the point of the minimal BMI that comes at 5–6 years old on average.[41] There is a consensus that early adiposity rebound predicts diabetes and obesity in adulthood [42, 43] although discussion continues about whether the reason for undesirable outcomes at adult age is due to children's lifestyles, [44] to their foetal lives [45] or to other causal mechanisms. [46] Hence, if earlier adiposity rebound indeed occurs in a subset of children after natural disasters due to lack of diet and exercise, administrative agencies and local paediatricians should pre-emptively address this source of future cardiovascular diseases. Because being physically active during the preschool ages reduces BMI over a long term. [47] in the immediate aftermath of an earthquake, play space availability should be ensured, balanced diets should be supplied, and schools should be reopened at the earliest possible date. Additionally, endocrinological and metabolic abnormalities often appear in preschool children with a 12-month history of being overweight.[48] Indeed, stress experienced in early childhood can persist and cause future neurologic and endocrine-related cardiovascular disease.[49] Thus, paediatricians need to assure long term follow-up and pay close attention to the health of children affected by a disaster.

#### 359 Limitations and strengths

The present study had several limitations. The primary limitation was the representativeness of the sample populations in affected prefectures of northeast Japan. The registered children with available data attended nursery schools that responded to the letter of request. Therefore, the data did not include children who died; those in destroyed nursery schools, nursery schools without schoolteachers or other deficiencies or those who had moved away from the area. Because data were not available indicating whether the most severely affected children Page 21 of 42

#### **BMJ Open**

Yokomichi H et al.

366	gained or lost weight, the direction and the amount of this bias in BMI were not determined.
367	Conversely, the study design could have specifically focused on children who experienced
368	severe suffering. Because of the study design, the definition of 'affected' children did not
369	identify those who were evacuated to provisional houses or who were physically impacted by
370	the tsunami. Therefore, the observed influence of the disaster on their child growth may have
371	been diminished, and the data may not reflect all children in the affected prefectures.
372	However, if the bias should exist, the effects of the earthquake on BMIs would be attenuated
373	according to the observed data and bias toward the null hypothesis. Thus, we consider that
374	the conclusions from the attenuated results would be held. Additionally, because nursery
375	schools in Japan require that either both parents or a single parent without spouse should be
376	employed, nursery school students may not represent the socio-economic status of all
377	children in the studied prefectures. Therefore, although the comparisons of nursery school
378	students in northeast Japan can be internally valid, it may not be possible to generalise the
379	results to all preschool children who will be affected by another disaster. Second, the lack of
380	information on diet and physical activity may limit the comparability of outcomes between
381	the affected and unaffected prefectures studied. Because the Pacific Ocean side of northeast
382	Japan receives less snow than the opposite side, exercise may be more frequent in the
383	affected prefectures than in the unaffected prefectures. This cultural factor may induce bias
384	toward decreasing BMIs of the affected children residing on the Pacific Ocean side.
385	Considering this negative bias in BMI, the weight gains among children living in Fukushima
386	and Iwate might be larger, and the weight loss observed in Miyagi might be smaller than
387	thought. Because there is no published data for the difference in BMI between growing
388	children residing on the Pacific Ocean side or the other side of northeast Japan, the amount of
389	this potential bias was undetermined. To correct for this potential bias, study initiation with a
390	matching method based on cultural confounders for a quasi-experimental design might have

Yokomichi H et al.

reduced the bias. Even so, we minimised the bias by selecting an unaffected reference group from the northeast Japan, where the diet was considered to be similar to that in the three affected prefectures.[50] Finally, the results were limited with no use of z score (standard deviation score) for BMI [51-53] which might have more properly adjusted for age. Although the standardisation by z score may be ideal for comparison of raw BMI values, the need for comparison of the BMI changes did not allow us to use the standardisation. Thus, we instead chose to compare BMI changes between two groups and make the simple adjustment of a covariate for months of age in the model.

The assembled longitudinal data would be strengthened by its uniqueness in recording child growth before and after a disaster. Although medical attention to the physical and mental health of people affected by a disaster has recently increased, surveys pertaining to this particular disaster have just begun. [54] A number of studies originating from these surveys should provide evidence to bolster disaster medicine. Another strength of this study is comparison of affected children with the unaffected children, who were considered to have been normally growing. For example, although one report described the health status of Iraqi refugees before immigration to the U.S. with an obesity prevalence of 24.6% and a hypertension prevalence of 15.2%, [55] the lack of information on unaffected Iraqis prevented an estimation of the influence of refugee life on human health. Similarly, the impact of a study that reported a high prevalence of mental disorders in Iraqi children during a war, [56] would be weakened because of the lack an unexposed comparator reference group. The evaluation of BMIs in growing children is usually difficult. However, we believe that an epidemiological answer has been provided to the study question on whether children's BMIs were influenced by the disaster. Furthermore, the phenomenon of an increased prevalence of overweight early-year primary school children in Fukushima has been observed in the ecological study. Although an ecological fallacy may exist, it is interesting that this

-----------	------	-----

416 phenomenon has appeared in Fukushima, where there are reports of delayed reconstruction.

#### 418 Conclusion

- The data from earthquake-stricken northeast Japan have shown an immediate increase in BMI
- 420 among children living in three affected prefectures. The data have also indicated trends of
- 421 prolonged BMI increases among children in Fukushima and prolonged BMI decreases among
- 422 children in Miyagi. These data emphasise the need for attention to and follow-up for affected
- 423 children after a natural disaster to prevent undesirable health outcomes.

of the circles are proportional to the population size.

Figure 2 Mean body mass indices (BMIs) of nursery school children born between 2 April
2006 and 1 April 2007 in each affected prefecture versus unaffected prefectures in northeast
Japan.

Figure 3 Estimated changes in body mass index (Diff BMI) after October 2010 among nursery school children born between 2 April 2006 and 1 April 2007 in each affected prefecture versus unaffected prefectures in northeast Japan. Statistical tests evaluated the *P* values of the interaction terms in the model. \* P < 0.05, \*\* P < 0.01 and \*\*\* P < 0.001.

Figure 4 Prevalence of overweight and obese children in Fukushima, Miyagi and Iwate prefectures (red lines) and the unaffected prefectures (blue lines). Solid and dashed lines represent the prevalence of overweight and obese children, respectively. Overweight and obese were diagnosed according to the child growth standards of the World Health Organization.[17] \* P < 0.05, \*\* P < 0.01 and \*\*\* P < 0.001.

## STROBE Statement-checklist of items that should be included in reports of observational studies

	Item No.	Recommendation	Page No.	Relevant text from manuscript
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	3	Line 39
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	3	Line 49–59
Introduction				
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	6	Line 74–90
Objectives	3	State specific objectives, including any prespecified hypotheses	6	Line 90–94
Methods				
Study design	4	Present key elements of study design early in the paper	8	Line 139–142
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure,		
		follow-up, and data collection	7	Line 101–106, 111–112
Variables	0	<ul> <li>(a) Cohort study—Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up</li> <li><i>Case-control study</i>—Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls</li> <li><i>Cross-sectional study</i>—Give the eligibility criteria, and the sources and methods of selection of participants</li> <li>(b) Cohort study—For matched studies, give matching criteria and number of exposed and unexposed</li> <li><i>Case-control study</i>—For matched studies, give matching criteria and the number of controls per case</li> </ul>	7	Line 112–114 NA
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	8–9	Line 139–149
Data sources/	8*	For each variable of interest, give sources of data and details of methods of assessment		
measurement		(measurement). Describe comparability of assessment methods if there is more than one group	7	Line 106–111
Bias	9	Describe any efforts to address potential sources of bias	9	Line 148
Study size	10	Explain how the study size was arrived at	10-11	Line 182–185, 193–199

AT-LZE Townloaded from http://bmjopen.2013-0105 on 7 April 2016. Downloaded from http://bmjopen.bmj.com/ on June 5, 2025 at Department GEZ-LTA Erasmushogeschool Protected by copytighteing/fackgesig/ated interfaction/file/fackings and single from http://bmiopen.bm/

Quantitative	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which		
variables		groupings were chosen and why	8	Line 135–139
Statistical	12	(a) Describe all statistical methods, including those used to control for confounding	8–9	Line 131–149
methods		(b) Describe any methods used to examine subgroups and interactions	8	Line 146–147
		(c) Explain how missing data were addressed	7	Line 113–114
		(d) Cohort study—If applicable, explain how loss to follow-up was addressed		
		Case-control study—If applicable, explain how matching of cases and controls was addressed		
		Cross-sectional study—If applicable, describe analytical methods taking account of sampling		
		strategy		NA
		( <u>e</u> ) Describe any sensitivity analyses		NA
Results				
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible,		
		examined for eligibility, confirmed eligible, included in the study, completing follow-up, and	10-11	Line 182–185, 193–19
		(b) Give reasons for non-participation at each stage	7	Line 113–114
		(c) Consider use of a flow diagram		NA
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information		
		on exposures and potential confounders	11	Table 1
		(b) Indicate number of participants with missing data for each variable of interest		NA
		(c) Cohort study—Summarise follow-up time (eg. average and total amount)	8	Line 132–135
Outcome data	15*	Cohort study—Report numbers of outcome events or summary measures over time		
			Supplementary Materials	Supplementary Table 1
		Case-control study—Report numbers in each exposure category, or summary measures of		NA
		exposure		
		Cross-sectional study—Report numbers of outcome events or summary measures		NA
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their		
		precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and		
		why they were included	11–13	Table 2
		(b) Report category boundaries when continuous variables were categorized	32, Figure 4, legend	Line 615–619

		time period		NA
Continued on next	17	Report other analyses done-eg analyses of subgroups and interactions, and sensitivity analyses		NA
page Other				
analyses				
Discussion				
Key results	18	Summarise key results with reference to study objectives	13–14	Line 255–270
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss		
		both direction and magnitude of any potential bias	19–21	Line 359–397
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of		
		analyses, results from similar studies, and other relevant evidence	18–19	Line 334–356
Generalisability	21	Discuss the generalisability (external validity) of the study results	19–20	Line 359–378
Other informati	on			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the		
		original study on which the present article is based	23	Line 433-437
*Give informatio	n sep	arately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in	n cohort and cross-section	onal studies.
